**Freescale Semiconductor**
Application Note

# Samba in Linux on a Sandpoint

*NCSG/DSD Applications*
*Freescale Semiconductor, Inc.*
*Austin, TX*

This application note describes the steps for obtaining, building, downloading, installing, and starting Samba on Linux on the Sandpoint platform. After completing these steps, one can run the Sandpoint Linux platform as a Samba server for Windows platforms on PCs.

This document addresses Samba 3.0.1, and it is assumed that the reader has installed Linux on a Sandpoint platform (application note AN2578 "Creating a Linux 'Out of the Box' Experience on a Sandpoint Platform," describes that process).

**Contents**

*freescale*™
*semiconductor*

# 1 Introduction

If using Sandpoint Linux with a preinstalled Samba server, read Section 7, "Cold-Starting Linux with Samba," first.

The following description of Samba is taken from the README file.

What is Samba, SMB/CIFS?

The very short answer is that it is the protocol by which a lot of PC-related machines share files and printers and other information such as lists of available files and printers. Operating systems that support this natively include Windows 9x, Windows NT (and derivatives), OS/2, MacOS X and Linux. Add-on packages that achieve the same are available for DOS, Windows 3.1, VMS, Unix of all kinds, MVS, and more. Some web browsers can speak this protocol as well (smb://). Alternatives to SMB include Netware, NFS, Appletalk, Banyan Vines, Decnet, and so on. Many of these have advantages, but none are both public specifications and widely implemented in desktop machines by default.

The Common Internet File System (CIFS) is what the new SMB initiative is called. For details, watch http://samba.org/cifs.

What are the uses of SMB?

- Many people want to integrate their Microsoft desktop clients with their Unix servers.
- Others want to integrate their Microsoft (and so on) servers with Unix servers. This is a different problem than integrating desktop clients.
- Others want to replace protocols like NFS, DecNet and Novell NCP, especially when used with PCs.

What can Samba do?

Here is a very short list of what Samba includes and what it does. For many networks this can be simply summarized by Samba to provide a complete replacement for Windows NT, Warp, NFS or Netware servers.

- A SMB server, to provide Windows NT and LAN Manager-style file and print services to SMB clients such as Windows 95, Warp Server, smbfs and others
- A Windows NT 4.0 domain controller replacement
- A file/print server that can act as a member of a Windows NT 4.0 or Active Directory domain.
- A NetBIOS (rfc1001/1002) name server that, amongst other things, gives browsing support. Samba can be the master browser on the LAN if preferred.
- A FTP-like SMB client to access PC resources (disks and printers) from UNIX, Netware, and other operating systems
- A tar extension to the client for backing up PCs
- Limited command-line tool that supports some of the NT administrative functionality, which can be used on Samba, a NT workstation, and a NT server

## 1.1    Terminology

This document uses the following terms:

| | |
|---|---|
| Bash shell | Extension to the Bourne shell, which is popular on Linux systems and is sometimes called GNU Born Again Bourne Shell. This shell is the default for most Linux systems because Linux uses GNU tools exclusively and is the best shell running the ISS. |
| Boot | Program that begins at hardware reset and prepares the hardware for loading an operating system |
| Boot address | Address from which the board attempts to boot after reset |
| Compiler | Software program that converts high-level source code into machine-specific binary |
| CPU | Central processor unit (that is, the processor) |
| CVS | Source control system |
| DINK32 | Small operating system debugger for the Sandpoint evaluation board |
| Host | Machine used to build kernels. The host may or may not be the same architecture. For example, Freescale builds kernels on G4 machines, UNIX machines, and Intel machines. |
| OS | Operating system |
| PCI | Peripheral component interface |
| PC | Personal computer |
| RAM | Random access memory |
| ROM/FLASH | Read-only memory / persistent memory |
| Server | Computer that holds and transfers objects, such as kernel objects. Can also be used as a host. |
| Windows | Microsoft operating system |

# 2    Obtaining a PowerPC™ Samba Source

Public sources of Linux for the PowerPC device (built on Power Architecture™ technology) are available on the following web sites:

1. http://www.samba.org/samba/whatsnew/samba-3.0.0.html
   This code tree is in the C language and is independent of the chip set. One code base is sufficient for all architectures. This URL always points to the latest version, which is currently 3.0.2.

2. http://www.samba.org
   One can navigate to the download sites from this web site and download Samba-3.0.2. This application note uses Samba-3.0.1, which is the first patch level of the all-new release. Samba-3.0.1 was released on 12/15/2003.

# 3    Building the Samba Executable

Assuming that a user has been created on the Sandpoint, use the following steps to do development on Samba on the Sandpoint.

1. Download the Samba source code.
   a)  Telnet into the Sandpoint running Linux to where building will occur.

**Samba in Linux on a Sandpoint,  Rev. 1**

    b) Prepare Linux for remote graphics support from the telneting machine.
`export DISPLAY=xxx.yyy.zzz.aaa`, where xxx.yyy.zzz.aaa is the IP address of the telneting machine (in this case, a Windows PC).

    c) Start Mozilla, which is similar to Netscape.
`mozilla`

    d) Navigate to a download site. The source code can be downloaded from the following link:
http://download.samba.org/samba/ftp/

    e) Download the tarball. Click the following link with the right mouse button:
\# samba-3.0.1.tar.bz2
Choose a location on the Linux machine to download the tarball.

    f) Exit Mozilla.

2. Unzip the tarball.

    a) The tarball is in bzip2 format and must be unzipped first.
`bunzip2 samba-3.0.1.tar.bz2`
This step converts samba-3.0.1.tar.bz2 to samba-3.0.1.tar.

    b) Untar the unzipped tarball.
`tar xvf samba-3.0.1.tar`
This step creates a Samba directory, samba_3.0.1, with all the source and make files necessary to build a Samba file system.

3. The following steps complete the Samba installation:

    a) Configure the build.
`build`
`install`
`configure samba`

    b) The following steps must be done in super user mode. Change to super user with the `su` command.

4. Configure the build.

    a) Go to the Samba directory.
`cd samba-3.0.1`
Note that many documents in the top level are helpful in understanding Samba. The manifest file describes the contents of the directory and contains instructions for configuring, building, and installing Samba.

    b) Configure the build using the standard Linux configure program.
`cd source`
`./configure`

5. Build. Make the executables.
`make`

6. Install the executables.
`make install`
This step installs the appropriate files and directories into the /usr/local/samba directory.

**NOTE**

If an old version of Samba exists, the make install renames all executables in usr/local/samba/bin and usr/local/samba/sbin to *.old. These files can be removed with the following commands:

```
cd /usr/local/samba
rm - rf *.old
```

# 4   Install Directory

Download, unzip, untar, and configure the build install. These steps usually proceed smoothly. Configuring the Samba server and turning it on, on the other hand, is a rather complex procedure that depends on the Samba configuration file. Fortunately, an example file can be modified for a specific system.

Before looking at the Samba configuration file, the installed Samba directory must be explored at /usr/local/samba. The following sections describe important directories and files located in this directory.

## 4.1   bin Directory

This directory contains all the executables for Samba, but just a few of them are discussed here. Point the PATH to the PATH=$PATH:/usr/local/samba/bin directory. Be aware of the following:

The smbpasswd executable creates Samba passwords for shared file directories. This action is the only way to implement shared directories that are accessible from Windows machines.

The testparm executable is the most important program while the Samba configuration is being attempted. This program processes the Samba configuration file, finds errors, and summarizes the final configuration.

The findsmb executable attempts to locate NetBIOS machines in the local network. The following is an example of findsmb output:

```
[root@8245SambaLinux bin]# findsmb

IP ADDR          NETBIOS NAME   WORKGROUP/OS/VERSION

---------------------------------------------------------------------
169.254.0.0      unknown nis name
10.82.117.1      TX32-0200        [SPS] [Windows 5.0] [Windows 2000 LAN Manager]
10.82.116.3      RA8136-02        [SPS] [Windows 5.0] [Windows 2000 LAN Manager]
10.82.117.6      TX32-0220        [SPS] [Windows 5.0] [Windows 2000 LAN Manager]
10.82.116.14     NCSDLAB-5        [SPS] [Windows NT 4.0] [NT LAN Manager 4.0]
10.82.116.15     TX32-0241        [SPS] [Windows 5.0] [Windows 2000 LAN Manager]
10.82.116.16     TX32-0240        [SPS] [Windows 5.0] [Windows 2000 LAN Manager]
```

## 4.2   include Directory

This directory includes the lone header file, libsmbclient.h.

## 4.3   lib

This is the most important directory because it is where the Samba configuration file resides. The testparm executable expects the configuration file to be in this directory. The Samba configuration file is smb.conf and is discussed in Section 5, "Configuring the Samba Server."

Unfortunately, the build procedure does not place a default smb.conf file in this directory. Copy it from Samba-3.0.1/examples/simple into this directory.

All the various message formats for swat are in this directory with the names xx.msg, where xx determines the language (for example, fr for french, ja for japanese, en for english).

## 4.4   man

This directory contains all the man pages for Samba. Set the MANPATH to point to the following: export MANPATH=$MANPATH:/usr/local/samba/man

## 4.5   private

This directory contains the Samba password file, smbpasswd. The smbpasswd commands use this file to remember passwords for file-sharing access.

## 4.6   sbin

This directory contains the commands for starting and stopping Samba and swat. The root user should point to this directory with the PATH variable as follows:

PATH=$PATH:/usr/local/samba/sbin

## 4.7   swat

This directory contains all the swat files. The swat system is a system where a web server is used to debug the Samba configuration. The most important subdirectory is /usr/local/samba/swat/using_samba, which contains the definitive Samba user's manual in HTML format for easy browsing on the web (see Section 9, "References," number 7 and its note). Start a web browser at the inx.html file to get a context-sensitive manual. Information about using swat can be found by pointing the browser to file:///usr/local/samba/swat/help/SWAT.html. These files are also available in the Samba source at samba_3.01/docs/htmldocs/using_samba.

## 4.8   var

This directory is most useful for debugging the configuration file. It contains the logs of all activity done by Samba. A log for the two daemons, log.nmbd and log.smbd, is included, along with a log for every IP address, name server name, and user that attempts to contact the Samba server. Perusing these logs can reveal when a problem occurs and aid the user in understanding the reason for the problem, which may lead to a method for solving a problem.

## 4.9 The .bashrc File

The user and the root each have a .bashrc file. This file is used to globally set the PATH and MANPATH variables for the login session. It includes the definitions for these two variables. In addition, the user can set any aliases and exports that are needed, such as the DISPLAY variable. The following is an example of a .bashrc file:

```
[root@SPlinux lib]# cat /root/.bashrc
# .bashrc

# User specific aliases and functions
alias rm='rm -i'
alias cp='cp -i'
alias mv='mv -i'
# Source global definitions
if [ -f /etc/bashrc ]; then
. /etc/bashrc
fi
alias ls='ls -F'
export MANPATH=$MANPATH:/usr/local/samba/man
export PATH=$PATH:/usr/local/samba/bin:/usr/local/samba/sbin
export DISPLAY=10.82.124.155:0.0
```

# 5 Configuring the Samba Server

Several shared directories or shared printers can be configured in the smb.conf file.

Remember that the Samba configuration file is smb.conf, and should reside in the /usr/local/samba/lib subdirectory. It can be somewhere else while pointing the appropriate commands to this alternate directory. A default smb.conf file is found in the source at samba-3.0.1/simple/smb.conf. This place is a good starting point. A complete description of the parameters for the smb.conf file is in Chapter 6 of the swat Samba manual, which is located at /usr/local/samba/swat/using_samba/ch06.html. A paper copy of any of these chapters can be created from any web browser that is displaying the chapter by using the File|Print... menu, or a text file can be created from the File|Save As... menu.

Copy the default Samba configuration file to the /usr/local/samba/lib directory:

cp samba-3.0.1/simple/smb.conf /usr/local/samba/lib

## 5.1 Sections of the smb.conf File

The smb.conf file is separated into several logical sections. A keyword surrounded by brackets [keyword] denotes each section. The following sections contain descriptions on the different sections.

### 5.1.1 [global]

The single line [global] denotes the first section, which defines global parameters. The settings for the global parameters that were set are shown below. Note that any parameters that are not specified in this section are unchanged from the default file.

1. workgroup = 8245GROUP, the name of the server. If a user accesses My Network Places on a Windows machine, this server appears as 8245GROUP.

2. server string = Samba Server, the NT description field.

3. security = user. This parameter indicates that Samba will run in the user mode. That is, each user must be authorized and verified at the initial login time of file sharing or printer requests.

4. log file = /usr/local/samba/log.%m
This parameter generates a separate log for each client.

### 5.1.2 [homes]

Denoted by the single line, [homes], this section defines the home directories that can be shared.

1. comment = Home Directories
A human-readable name

2. browseable = yes
Indicates that users can browse for these shared directories

3. writable = yes
Indicates that users can write into shared directories

### 5.1.3 [printers]

Denoted by the single line, [printers], this section defines shared printers.

comment = All Printers

A human-readable name. Each private printer can have a specific section. However, all BSD-style printers share the [printers] section.

**NOTE**

The directory, path = /usr/spool/samba, is used for spooling print jobs. It must exist, be owned by root, and have all permissions on so that print users can spool the print file here. If this directory does not exist, the user gets a 'no permission' error.

```
create directory /usr/spool/samba
permissions 777, i.e. all permissions
/usr needs permission of 755 and /usr/spool needs permissions of 777.
ls -ld /usr
[root@8245Sambalinux /]#
[root@8245Sambalinux /]# ls -ld usr
drwxr-xr-x   17 root     root          4096 Dec 18 10:36 usr/
[root@8245Sambalinux /]# ls -ld usr/spool
drwxr-xr-x    3 root     root          4096 Dec 18 10:36 usr/spool/
```

```
[root@8245Sambalinux /]# ls -ld usr/spool/samba/
drwxrwxrwx    2 root     root          4096 Dec 18 10:55 usr/spool/samba/
```

- browseable = yes
  Allows the printer to be browsed by clients
- public = yes
  Allows user guest account to print
- guest ok = yes
  Allows guest access to the printer
- writable = no
  Users cannot write to the printer; they can only print to the printer.
- printable = yes
  A user must be able to print to the printer.
- ./cups start
  Allows the cups facility to control the printer

## 5.2    Debugging the smb.conf File

Using an editor that displays color is very helpful for finding errors. Using the vi editor with the smb.conf file displays these colors. Sections are coded in gold, keywords in green, yes/no in red, and values in black.

The testparm program reads a smb.conf file and reports any errors. It also displays the service definitions that this smb.conf file generates.

The following example shows an error.

```
[root@SPlinux root]# testparm
Load smb config files from /usr/local/samba/lib/smb.conf
Unknown parameter encountered: "secutiry"
Ignoring unknown parameter "secutiry"
Processing section "[homes]"
Processing section "[printers]"
Loaded services file OK.
Server role: ROLE_STANDALONE
Press enter to see a dump of your service definitions
```

Notice that *secutiry* is spelled wrong.

This example shows no errors once the security line is corrected.

```
[root@SPlinux lib]# testparm
Load smb config files from /usr/local/samba/lib/smb.conf
Processing section "[homes]"
Processing section "[printers]"
Loaded services file OK.
Server role: ROLE_STANDALONE
Press enter to see a dump of your service definitions

# Global parameters
[global]

workgroup = 8245GROUP
server string = Samba Server
```

```
guest account = pcguest
log file = /usr/local/samba/log.%m

[homes]

comment = Home Directories
read only = No
create mask = 0750

[printers]

comment = All Printers
path = /usr/spool/samba
create mask = 0700
guest ok = Yes
printable = Yes
browseable = No
```

## 5.3    Example smb.conf File

The following smb.conf file is used in the previous example of testparm.

```
[root@SPlinux lib]# cat smb.conf

; Configuration file for smbd.

; =============================================================================

; For the format of this file and comprehensive descriptions of all the
; configuration option, please refer to the man page for smb.conf(5).

; The following configuration should suit most systems for basic usage and
; initial testing. It gives all clients access to their home directories and
; allows access to all printers specified in /etc/printcap.

; Things you need to check:
; -------------------------

; 1: Check the path to your printcap file. If you are using a system that does
;    not use printcap (eg., Solaris), create a file containing lines of the
;    form

;        printername|printername|printername|

;    where each "printername" is the name of a printer you want to provide
;    access to. Then alter the "printcap =" entry to point to the new file.

;    If using Solaris, the following command will generate a suitable printcap
;    file:

;        lpc status | grep ":" | sed s/:/\|/ > myprintcap
;

; 2: Make sure the "print command" entry is correct for your system. This
;    command should submit a file (represented by %s) to a printer
;    (represented by %p) for printing and should REMOVE the file after
;    printing.
```

```
;     One most systems the default will be OK, as long as you get "printing ="
;     right.

;     It is also a good idea to use an absolute path in the print command
;     as there is no guarantee the search path will be set correctly.
;

; 3: Make sure the "printing =" option is set correctly for your system.
;    Possible values are "sysv", "bsd" or "aix".
;

; 4: Make sure the "lpq command" entry is correct for your system. The default
;    may not work for you.
;

; 5: Make sure that the user specified in "guest account" exists. Typically
;     this will be a user that cannot log in and has minimal privileges.
;     Often the "nobody" account doesn't work (very system dependant).
;

; 6: You should consider the "security =" option. See a full description
;    in the main documentation and the smb.conf(5) manual page
;

; 7: Look at the "hosts allow" option, unless you want everyone on the internet
;    to be able to access your files.
;

[global]

   workgroup = 8245GROUP

   server string = Samba Server

   security = user

   printing = bsd

   printcap name = /etc/printcap

   load printers = yes

   guest account = pcguest
;  This next option sets a separate log file for each client. Remove

;  it if you want a combined log file.

   log file = /usr/local/samba/log.%m

;  You will need a world readable lock directory and "share modes=yes"

;  if you want to support the file sharing modes for multiple users

;  of the same files

;  lock directory = /usr/local/samba/var/locks
```

**Samba in Linux on a Sandpoint, Rev. 1**

Freescale Semiconductor                        11

```
;    share modes = yes

[homes]

    comment = Home Directories

    browseable = yes

    read only = no

    create mode = 0750

    writeable = yes

[printers]

    comment = All Printers

    path = /usr/spool/samba

    browseable = yes

    printable = yes

    public = yes

    writable = no

    create mode = 0700

; You might also want this one; notice that it is read only so as not to give

; people without an account write access.

;

; [tmp]

;    comment = Temporary file space

;    path = /tmp

;    read only = yes

;    public = yes

;

; Other examples:

;

; A private printer, usable only by fred. Spool data will be placed in fred's

; home directory. Note that fred must have write access to the spool directory,

; wherever it is.
```

```
;[fredsprn]

;    comment = Fred's Printer

;    valid users = fred

;    path = /homes/fred

;    printer = freds_printer

;    public = no

;    writable = no

;    printable = yes

;

; A private directory, usable only by fred. Note that fred requires write

; access to the directory.

;[fredsdir]

;    comment = Fred's Service

;    path = /usr/somewhere/private

;    valid users = fred

;    public = no

;    writable = yes

;    printable = no

;

; A publicly accessible directory, but read only, except for people in

; the staff group

;[public]

;    comment = Public Stuff

;    path = /usr/somewhere/public

;    public = yes

;    writable = no

;    printable = no

;    write list = @staff

;

; A service that has a different directory for each machine that connects.

; This allows you to tailor configurations to incoming machines. You could

; also use the %u option to tailor it by user name.
```

```
; The %m gets replaced with the machine name that is connecting.
;[pchome]
;   comment = PC Directories
;   path = /usr/pc/%m
;   public = no
;   writeable = yes
;
; A publicly accessible directory, read/write to all users. Note that all files
; created in the directory by users will be owned by the default user, so
; any user with access can delete any other user's files. Obviously this
; directory must be writable by the default user. Another user could of course
; be specified, in which case all files would be owned by that user instead.
;[public]
;   path = /usr/somewhere/else/public
;   public = yes
;   only guest = yes
;   writable = yes
;   printable = no
;
; The following two entries demonstrate how to share a directory so that two
; users can place files there that will be owned by the specific users. In this
; setup, the directory should be writable by both users and should have the
; sticky bit set on it to prevent abuse. Obviously this could be extended to
; as many users as required.
;[myshare]
;   comment = Mary's and Fred's stuff
;   path = /usr/somewhere/shared
;   valid users = mary fred
;   public = no
;   writable = yes
;   printable = no
```

```
;    create mask = 0765

[root@SPlinux lib]#
```

# 6    Controlling Samba and Users

The following sections discuss controlling Samba and how users use Samba.

## 6.1    Creating File Shares

To share files on the Samba server, it is necessary to create Samba user/password pairs. These pairs are created by the smbpassword command.

```
[root@SPlinux root]# smbpasswd -a maurie

New SMB password:

Retype new SMB password:

startsmbfilepwent_internal: file /usr/local/samba/private/smbpasswd did not exist.
File successfully created.

Added user maurie.

[root@SPlinux root]# smbpasswd -a joey

New SMB password:

Retype new SMB password:

Added user joey.

[root@SPlinux root]#
```

These commands create sharable directories for the two users, maurie and joey, which must exist and have home directories on the server.

**NOTE**

When connecting to a Samba share folder, only one user name at a time can be used in a single session.

Thus, a user can connect to joey's home directory or maurie's home directory but not both in a single Windows login session. The user must log out of Windows and log back in to see the other share, or log out of joey to log into maurie and vice versa.

It is necessary to be logged into one of these two shares to print from the Samba server printer.

## 6.2    Creating Printer Shares

To share a printer, create a printer share on the server. The easiest way is to use the interactive command, printtool. Remember from Section 3, "Building the Samba Executable," that the DISPLAY variable must

be exported before running this command. The following steps outline how to create a printer share on the server using printtool:

1. Run the printtool command.
2. Select the New button.
3. The 'Add a new print queue window' will open. Fill in the Name and Short Description label boxes. An example is provided below:

   Name: smbprinter8245

   Short Description: Canon400-BW in B2455 IP 10.82.119.224

   The name is what the users see on their Windows machine. The short description is just for documentation purposes.
4. Choose a queue type by pulling down the list box next to 'Select a Queue Type'. An example is as follows:

   Select a Queue Type: Networked JetDirect

   Alternatively, the user can select a local printer or any other type of networked printer as in the following example:

   Printer: 10.82.119.224

   Port: 9100

   This is the printer's IP address. Use the default port number, which is 9100 in this case.
5. Choose a printer model:

   Printer model: LaserJet 4Si/4Si MX

   The user should choose the correct printer driver, which is the Canon ImageWriter 400 in this case. However, there is no driver for it, so choose the HP LaserJet 4Si Mx instead. Choosing the wrong driver can cause garbage printing.
6. Apply the changes.

Now the printer is available on the Samba server. Commands that are useful while logged into the Samba server are as follows:

- lp <filename>

  Prints this filename on the printer
- lpq

  Shows which jobs are in the queue
- lpstat

  Shows the status of the queue
- lprm <job id>

  Cancels the printing of the job. Obtains the job ID from the lpq command, which lists all the print jobs in the queue. The job ID is under the heading 'Job'.

The following is an example of these commands:

```
[root@SPlinux root]# lpq
smbprinter8245 is ready
no entries
```

**Samba in Linux on a Sandpoint, Rev. 1**

```
[root@SPlinux root]# lpstat
[root@SPlinux root]# cd /usr/local/samba/lib
[root@SPlinux lib]# lp smb.conf
request id is smbprinter8245-2 (1 file(s))
[root@SPlinux lib]# lpq
smbprinter8245 is ready and printing

Rank    Owner   Job     File(s)                         Total Size
active  root    2       smb.conf                        6144 bytes
[root@SPlinux lib]# lpstat
smbprinter8245-2        root            6144    Sun 04 Jan 2004 05:26:11 PM EST
```

## 6.2.1    Problems with the Printer

If the queue becomes corrupted and printing does not work, stop and start cups.

```
cd /etc/init.d
./cups stop
./cups start
```

If the user gets any of the following errors while trying to use the printer on the server or cannot remotely connect to the printer, start cups.

```
[maurie@8245SambaLinux maurie]$ lpq
lpq: Unable to contact server!
[maurie@8245SambaLinux maurie]$ lpstat
lpstat: Unable to connect to server: Connection refused
[maurie@8245SambaLinux maurie]$ lp .bashrc
lp: error - no default destination available.
[maurie@8245SambaLinux maurie]$
```

Cups should now be stopped. Check the status of cups with the following command:

```
[root@8245SambaLinux root]# cd /etc/init.d
[root@8245SambaLinux init.d]# ./cups status
cupsd is stopped
```

Now start cups.

```
cd /etc/init.d
./cups start
```

If the remote user gets the error 'Could not start print job', the most likely error is that the /usr/spool/samba directory does not exist or has the wrong permissions. See Section 5.3, "Example smb.conf File" for more information.

## 6.3    Turning Samba On and Off

The following sections discuss starting and stopping the two daemons, smbd and nmbd.

**Samba in Linux on a Sandpoint,  Rev. 1**

# 6.3.1 Starting and Stopping the Daemons

Only the root user can start and stop the two daemons.

```
/usr/local/samba/sbin/smbd -D (or just smbd -D)
/usr/local/samba/sbin/nmbd -D (or just nmbd -D)
```

# 6.3.2 Verifying the Daemons

The following commands verify the daemons.

```
ps -ef | grep mbd
[root@8245Sambalinux lib]# ps -ef | grep mbd
root       860     1  0 14:11 ?        00:00:00 ./smbd -D
root       862     1  0 14:12 ?        00:00:00 ./nmbd -D
root      1078   860  0 15:23 ?        00:00:02 [smbd]
[root@8245Sambalinux lib]#
```

# 6.3.3 Killing the Daemons

Use the kill command and specify the PIDs of smbd and nmbd.

kill -9 860 862

# 6.3.4 Forcing the Daemons to Reread the smb.conf File

Normally, the daemons reread the smb.conf file every 60 seconds, but to force a quicker read use the following command:

killall -HUP smbd nmbd

Note that the smb.conf file is dynamic. Changes while the daemons are running take effect within 60 seconds.

# 6.3.5 Log Files

After running Samba for some time and after users have started sharing files and printers, a series of log files are generated in the /usr/local/samba/var directory. See the following example:

```
[root@8245SambaLinux init.d]# cd /usr/local/samba/var

[root@8245SambaLinux var]# ls

locks/              log.10.82.124.155   log.appslab12     log.rzvx90-02

log.10.82.117.255   log.10.82.242.208   log.appslabpc07   log.smbd

log.10.82.118.239   log.127.0.0.1       log.nmbd

log.10.82.119.177   log.8245sambalinux  log.r18795-11
```

Notice that logs are produced for all IP address machines and/or named machines that attempt access and for all users (for example log.rzvx90-02, and the daemons, smbd and nmbd). Most of the logs are empty because no problems or useful activity occurred.

## 6.3.5.1  Useful Logs

Some of the more useful logs are shown below:

**log.appslabpc07** (a machine used to access file shares)

```
[2003/12/18 08:55:07, 1] smbd/service.c:make_connection_snum(698)

  appslabpc07 (10.82.117.255) connect to service joey initially as user joey (uid=504,
gid=504) (pid 1956)

[2003/12/18 08:55:24, 1] smbd/service.c:close_cnum(880)

  appslabpc07 (10.82.117.255) closed connection to service joey

[2004/01/06 08:34:20, 1] smbd/service.c:make_connection_snum(698)

   appslabpc07 (10.82.117.255) connect to service maurie initially as user maurie
(uid=503, gid=503) (pid 617)

[2004/01/06 08:37:00, 1] smbd/service.c:close_cnum(880)

  appslabpc07 (10.82.117.255) closed connection to service maurie
```

**log.nmbd**

```

**NOTE**

Logs are not rewritten from the beginning when the daemons are stopped and started. Delete a log to remove previous log information.

## 6.4    Accessing Files and Printers on a Windows PC

Files and printers can be remotely accessed from the server. In this example, two users (maurie and joey) are sharable on the server. One printer, smbprinter8245, is available.

Only one user per session can be shared on a Windows PC.

### 6.4.1    Sharing a Home Directory from the Samba Server

The steps to share a home directory from the Samba server on a Windows machine are outlined below.

1. Open Windows Explorer.
2. Open the Map Network Drive Dialog Tools|Map Network Drive menu item.
3. Specify the folder. If the Samba server is known by a name server, use the workgroup name specified in the smb.conf file; if not, specify the IP address. Also specify the share name.
The order is Folder: \\server\share.
An example of how to specify the folder for the smb.conf file and users specified in this application note is as follows:
When a name server is available: Folder: \\8245GROUP\maurie, or
Using an arbitrary IP: Folder: \\xx.yy.zz.aa\maurie and Folder: \\10.82.118.239\maurie.
The joey share can be specified as Folder: \\10.82.118.239\joey.
4. Select Connect using a different user unless the Windows login name and password are the same as the Samba login and password.
5. Select Finish.
6. The shared home directory is now available on the Windows Explorer window under the drive letter designated in the Map Network Drive dialog box.
7. This drive can be disconnected with the Tools|Disconnect Network Drive dialog box.

## 6.4.2 Sharing a Printer from the Samba Server

1. Open the printer dialog box on the Windows machine.
   Use the Start|Settings|Printers and Faxes|Add Printer menu item.

2. Select a network printer.

3. Select Connect to connect to this printer.

4. Name: Depending on whether the Samba server is known to a name server or not, use the workgroup name or the IP address.
   Name: \\8245GROUP\smbprinter8245, or
   Name: \\10.82.118.239\smbprinter8245

5. If the user gets a message about the incorrect printer driver, click OK and assign a driver. In this case, the Canon ImageWriter 400 does not have a driver, but the HP 4Si can be used.

6. Choose whether to make this printer the default printer.

7. Access this printer from any Windows application that can print.

8. As an example, use Wordpad as described in the following steps:
   Open Wordpad.
   Type in some text such as 'This is a test on Samba 8245'.
   Print it using the File|Print... menu item. Select the smbprinter8245 or whatever it was named.
   Retrieve the listing.

9. It is possible to disconnect from this printer with the Start|Settings|Printers and Faxes menu item. Select the smbprinter8245 or whatever it was named, right click, and choose Delete.

# 7 Cold-Starting Linux with Samba

When all the Samba configuration, share passwords, and printers are installed and ready for use and the Samba daemons are started on a running system, remote access is available and ready to go.

However, if the Linux machine is shut down, the printer daemon, cups, and Samba daemons, smbd and nmbd, are not started on Linux boot unless an init is set up to start them. This paper does not discuss autostarting these three daemons.

Whenever the Linux Samba server is rebooted, activate the restart cups and Samba and verify their operation with the following commands:

```
[root@8245SambaLinux init.d]# cd /etc/init.d

[root@8245SambaLinux init.d]# ./cups start

Starting cups:                                                [  OK  ]

[root@8245SambaLinux init.d]# lpstat

[root@8245SambaLinux init.d]# lpq

smbprinter8245 is ready

no entries

[root@8245SambaLinux init.d]#
```

```
[root@8245SambaLinux init.d]# smbd -D

[root@8245SambaLinux init.d]# nmbd -D

[root@8245SambaLinux init.d]# ps -ef | grep mbd

root       752    1  1 09:57 ?        00:00:00 smbd -D

root       754    1  0 09:57 ?        00:00:00 nmbd -D

root       756  660  0 09:57 pts/0    00:00:00 grep mbd

[root@8245SambaLinux init.d]#
```

The Samba binaries are installed into /usr/local/samba. If they are missing, the tar file, samba3_0_1_bin.tar, located on partition 4 of the hard drive, /dev/hda4, can be untarred to /usr/local.

Now the server is ready for remote logins and remote printer usage.

# 8   Conclusion

This paper has presented all the pertinent information for downloading, building, and configuring a Samba server for Linux on a Sandpoint system. Samba is a file and print server running on Linux to support sharing on Windows machines.

- For assistance with this application note, contact a Freescale representative at the website listed on the back page.
- For more detailed questions about Samba, see the E-mail list site used specifically for this purpose. These lists are informally maintained by Samba developers and others and are not affiliated with Freescale. See http://lists.samba.org/.
