

## APPENDIX A

### ELECTRICAL CHARACTERISTICS

This appendix contains electrical specification tables and reference timing diagrams for the MC68332 and the MC68LK332.

**Table A-1 Maximum Ratings**

Num	Rating	Symbol	Value	Unit
1	Supply Voltage <sup>1, 2, 7</sup>	$V_{DD}$	-0.3 to + 6.5	V
2	Input Voltage <sup>1, 2, 3, 5, 7</sup>	$V_{in}$	-0.3 to + 6.5	V
3	Instantaneous Maximum Current Single pin limit (applies to all pins) <sup>1, 5, 6, 7</sup>	$I_D$	25	mA
4	Operating Maximum Current Digital Input Disruptive Current <sup>4, 5, 6, 7, 8</sup> $V_{NEGCLAMP} \equiv -0.3$ V $V_{POSCLAMP} \equiv V_{DD} + 0.3$	$I_{ID}$	-500 to 500	$\mu$ A
5	Operating Temperature Range MC68332 No Suffix MC68332 "C" Suffix MC68332 "V" Suffix MC68332 "M" Suffix	$T_A$	$T_L$ to $T_H$ 0 to 70 -40 to 85 -40 to 105 -40 to 125	$^{\circ}$ C
6	Storage Temperature Range	$T_{stg}$	-55 to 150	$^{\circ}$ C

**NOTES:**

1. Permanent damage can occur if maximum ratings are exceeded. Exposure to voltages or currents in excess of recommended values affects device reliability. Device modules may not operate normally while being exposed to electrical extremes.
2. Although sections of the device contain circuitry to protect against damage from high static voltages or electrical fields, take normal precautions to avoid exposure to voltages higher than maximum-rated voltages.
3. All pins except TSTME/TSC.
4. All functional non-supply pins are internally clamped to  $V_{SS}$ . All functional pins except EXTAL, TSC, and XFC are internally clamped to  $V_{DD}$ .
5. Input must be current limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values for positive and negative clamp voltages, then use the larger of the two values.
6. Power supply must maintain regulation within operating  $V_{DD}$  range during instantaneous and operating maximum current conditions.
7. This parameter is periodically sampled rather than 100% tested.
8. Total input current for all digital input-only and all digital input/output pins must not exceed 10 mA. Exceeding this limit can cause disruption of normal operation.

**Table A-6 Thermal Characteristics**

Num	Characteristic	Symbol	Value	Unit
1	Thermal Resistance	$\Theta_{JA}$		$^{\circ}\text{C/W}$
	Plastic 132-Pin Surface Mount		38	
	Plastic 144-Pin Surface Mount		46	
	Thin Plastic 144-Pin Surface Mount		49	

The average chip-junction temperature ( $T_J$ ) in C can be obtained from:

$$T_J = T_A + (P_D \times \Theta_{JA}) \quad (1)$$

where:

$T_A$  = Ambient Temperature,  $^{\circ}\text{C}$

$\Theta_{JA}$  = Package Thermal Resistance, Junction-to-Ambient,  $^{\circ}\text{C/W}$

$P_D = P_{INT} + P_{I/O}$

$P_{INT} = I_{DD} \times V_{DD}$ , Watts — Chip Internal Power

$P_{I/O}$  = Power Dissipation on Input and Output Pins — User Determined

For most applications  $P_{I/O} < P_{INT}$  and can be neglected. An approximate relationship between  $P_D$  and  $T_J$  (if  $P_{I/O}$  is neglected) is:

$$P_D = K \div (T_J + 273^{\circ}\text{C}) \quad (2)$$

Solving equations 1 and 2 for K gives:

$$K = P_D \times (T_A + 273^{\circ}\text{C}) + \Theta_{JA} \times P_D^2 \quad (3)$$

where K is a constant pertaining to the particular part. K can be determined from equation (3) by measuring  $P_D$  (at equilibrium) for a known  $T_A$ . Using this value of K, the values of  $P_D$  and  $T_J$  can be obtained by solving equations (1) and (2) iteratively for any value of  $T_A$ .

**NOTES:**

1. All internal registers retain data at 0 Hz.
2. This parameter is periodically sampled rather than 100% tested.
3. Assumes that a low-leakage external filter network is used to condition clock synthesizer input voltage. Total external resistance from the XFC pin due to external leakage must be greater than 15 M $\Omega$  to guarantee this specification. Filter network geometry can vary depending upon operating environment.
4. Proper layout procedures must be followed to achieve specifications.
5. Assumes that stable  $V_{DDSYN}$  is applied, and that the crystal oscillator is stable. Lock time is measured from the time  $V_{DD}$  and  $V_{DDSYN}$  are valid until RESET is released. This specification also applies to the period required for PLL lock after changing the W and Y frequency control bits in the synthesizer control register (SYNCR) while the PLL is running, and to the period required for the clock to lock after LPSTOP.
6. Internal VCO frequency ( $f_{VCO}$ ) is determined by SYNCR W and Y bit values. The SYNCR X bit controls a divide-by-two circuit that is not in the synthesizer feedback loop. When X = 0, the divider is enabled, and  $f_{sys} = f_{VCO} \div 4$ . When X = 1, the divider is disabled, and  $f_{sys} = f_{VCO} \div 2$ . X must equal one when operating at maximum specified  $f_{sys}$ .
7. Jitter is the average deviation from the programmed frequency measured over the specified interval at maximum  $f_{sys}$ . Measurements are made with the device powered by filtered supplies and clocked by a stable external clock signal. Noise injected into the PLL circuitry via  $V_{DDSYN}$  and  $V_{SS}$  and variation in crystal oscillator frequency increase the  $J_{clk}$  percentage for a given interval. When jitter is a critical constraint on control system operation, this parameter should be measured during functional testing of the final system.

- Does not apply to  $\overline{\text{HALT}}$  and  $\overline{\text{RESET}}$  because they are open drain pins.  
Does not apply to Port QS[7:0] (TXD, PCS[3:1], PCS0/SS, SCK, MOSI, MISO) in wired-OR mode.
- Current measured at maximum system clock frequency.
- Total operating current is the sum of the appropriate V<sub>DD</sub> supply and V<sub>DDSYN</sub> supply current.
- When V<sub>SB</sub> is more than 0.3V greater than V<sub>DD</sub>, current flows between the V<sub>STBY</sub> and V<sub>DD</sub> pins, which causes standby current to increase toward the maximum condition specification. System noise on the V<sub>DD</sub> and V<sub>STBY</sub> pin can contribute to this condition.
- The SRAM module will not switch into standby mode as long as V<sub>SB</sub> does not exceed V<sub>DD</sub> by more than 0.5 volts. The SRAM array cannot be accessed while the module is in standby mode.
- Power dissipation measured with external clock at maximum specified system clock frequency, all modules active. Power dissipation can be calculated using the expression:  
 $P_D = 3.6V (I_{\text{DDSYN}} + I_{\text{DD}})$   
I<sub>DD</sub> includes supply currents for all device modules powered by V<sub>DD</sub> pins
- Input capacitance is periodically sampled rather than 100% tested.

**NOTES:**

- Applies to :  
Port E[7:4] —  $\overline{SIZ}[1:0]$ ,  $\overline{AS}$ ,  $\overline{DS}$   
Port F[7:0] —  $\overline{IRQ}[7:1]$ , MODCLK  
Port GP[7:0] — IC4/OC5/OC1, IC[3:1], OC[4:1]/OC1  
Port QS[7:0] — TXD, PCS[3:1], PCS0/SS, SCK, MOSI, MISO  
Other: BKPT/DSCLK,  $\overline{IFETCH}$ ,  $\overline{RESET}$ , RXD, TSC, EXTAL (when PLL enabled)
- Input-Only Pins: EXTAL, TSC, BKPT/DSCLK, RXD  
Output-Only Pins: CSBOOT, BG/CS, CLKOUT, FREEZE/QUOT,  $\overline{IPIPE}$   
Input/Output Pins:  
Group 1: Port GP[7:0] — IC4/OC5/OC1, IC[3:1], OC[4:1]/OC1  
Other: DATA[15:0],  $\overline{IFETCH}$   
Group 2: Port C[6:0] — ADDR[22:19]/CS[9:6], FC[2:0]/CS[5:3]  
Port E[7:0] —  $\overline{SIZ}[1:0]$ ,  $\overline{AS}$ ,  $\overline{DS}$ , AVEC, RMC,  $\overline{DSACK}[1:0]$   
Port F[7:0] —  $\overline{IRQ}[7:1]$ , MODCLK  
Port QS[7:3] — TXD, PCS[3:1], PCS0/SS  
Other: ADDR23/CS10/ECLK, ADDR[18:0], R/W,  $\overline{BERR}$ ,  $\overline{BR}/CS0$ ,  $\overline{BGACK}/CS2$   
Group 3: HALT,  $\overline{RESET}$   
Group 4: MISO, MOSI, SCK
- Does not apply to HALT and  $\overline{RESET}$  because they are open drain pins. Does not apply to Port QS[7:0] (TXD, PCS[3:1], PCS0/SS, SCK, MOSI, MISO) in wired-OR mode.
- Current is measured at a specified system clock frequency, all modules active.
- Use of an active pulldown device is recommended.
- Total operating current is the sum of the appropriate  $I_{DD}$ ,  $I_{DDSYN}$  values.  $I_{DD}$  values include supply currents for device modules powered by  $V_{DD}$ .
- Power dissipation is measured with external clock at maximum specified system clock frequency, all modules active. Power dissipation can be calculated using the following expression:  
$$P_D = \text{Maximum } V_{DD} (I_{DD} + I_{DDSYN})$$
  
 $I_{DD}$  includes supply currents for all device modules powered by  $V_{DD}$  pins.
- This parameter is periodically sampled rather than 100% tested.

**NOTES:**

1. All AC timing is shown with respect to V<sub>IH</sub>/V<sub>IL</sub> levels unless otherwise noted.
2. When an external clock is used, minimum high and low times are based on a 50% duty cycle. The minimum allowable t<sub>x<sub>cyc</sub></sub> period is reduced when the duty cycle of the external clock varies. The relationship between external clock input duty cycle and minimum t<sub>x<sub>cyc</sub></sub> is expressed:  
Minimum t<sub>x<sub>cyc</sub></sub> period = minimum t<sub>x<sub>CHL</sub></sub> / (50% – external clock input duty cycle tolerance).
3. Specification 9A is the worst-case skew between  $\overline{\text{AS}}$  and  $\overline{\text{DS}}$  or  $\overline{\text{CS}}$ . The amount of skew depends on the relative loading of these signals. When loads are kept within specified limits, skew will not cause  $\overline{\text{AS}}$  and  $\overline{\text{DS}}$  to fall outside the limits shown in specification 9.
4. If multiple chip-selects are used,  $\overline{\text{CS}}$  width negated (specification 15) applies to the time from the negation of a heavily loaded chip-select to the assertion of a lightly loaded chip select. The  $\overline{\text{CS}}$  width negated specification between multiple chip-selects does not apply to chip selects being used for synchronous ECLK cycles.
5. Hold times are specified with respect to  $\overline{\text{DS}}$  or  $\overline{\text{CS}}$  on asynchronous reads and with respect to CLKOUT on fast cycle reads. The user is free to use either hold time.
6. Maximum value is equal to (t<sub>cyc</sub> / 2) + 25 ns.
7. If the asynchronous setup time (specification 47A) requirements are satisfied, the  $\overline{\text{DSACK}}[1:0]$  low to data setup time (specification 31) and  $\overline{\text{DSACK}}[1:0]$  low to  $\overline{\text{BERR}}$  low setup time (specification 48) can be ignored. The data must only satisfy the data-in to clock low setup time (specification 27) for the following clock cycle.  $\overline{\text{BERR}}$  must satisfy only the late  $\overline{\text{BERR}}$  low to clock low setup time (specification 27A) for the following clock cycle.

8. To ensure coherency during every operand transfer,  $\overline{BG}$  is not asserted in response to  $\overline{BR}$  until after all cycles of the current operand transfer are complete.
9. In the absence of  $\overline{DSACK}[1:0]$ ,  $\overline{BERR}$  is an asynchronous input using the asynchronous setup time (specification 47A).
10. After external  $\overline{RESET}$  negation is detected, a short transition period (approximately  $2 t_{cyc}$ ) elapses, then the SIM drives  $\overline{RESET}$  low for  $512 t_{cyc}$ .
11. External assertion of the  $\overline{RESET}$  input can overlap internally-generated resets. To insure that an external reset is recognized in all cases,  $\overline{RESET}$  must be asserted for at least 590 CLKOUT cycles.
12. External logic must pull  $\overline{RESET}$  high during this period in order for normal MCU operation to begin.
